

ABSTRACT

A bending apparatus is especially adapted for mounting to a vise to hold the bending apparatus in an aligned position so that the bending apparatus may impart a desired angle bend on a workpiece. The bending apparatus includes an orienting member
5 with a cross-sectional shape to complement the shape of the vice jaws. The bending apparatus when secured in the vise jaws is oriented horizontally or vertically, thus enabling the bending apparatus to precisely create horizontal and vertical bends in a workpiece. Bends may be created in succession without requiring a user to continually adjust the orientation of the workpiece or the bending apparatus itself.
